

## KNN (K-Nearest Neighbour)

$f_1$     $f_2$     $y (0/1)$

Steps:

1) Determine the  $k$ -value

$$\cancel{k=0} \quad 0 \rightarrow \infty \quad \underline{0 < k \leq \infty}$$

2) Calculate the nearest neighbour of the test data (No. of neighbour will depend on  $k$ ).

3) Count the no. of points which belong to 0 category & 1 category.

Whichever is greater, the test data will belong to that category.

Q How to calculate  $k$ -nearest neighbour?

1) For Euclidean distance

2) Ham Manhattan distance

Euclidean formula (Mostly used in airlines).

$$x_1, y_1$$

$$x_2, y_2$$

$$\sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2}$$

Manhattan distance:

$$|x_1 - x_2| + |y_1 - y_2|$$

KNN - Classification we have seen rightly now.

KNN Regression:

step: we will compute the distance for test data. (nearest)

- Take the average of these points

## KNN Optimization:

- In order to find the nearest neighbour, we don't need to find the distance from all the points. (Time complexity -  $O(n)$ ).

we can optimize this by using:

- KD Tree
- Ball Tree.

### KD Tree:

It splits the data recursively according to the axes (Creates a BST).

Then, the new test data is searched.

In KD Tree, we have to backtrack to the datapoints.

### Ball Tree:

- It creates group of nearest points.
- This process is repeated till all the datapoints are covered.
- Whenever the new data comes, the group is checked and the nearest

neighbors are then selected.

- This doesn't require back-tracking.
